ABSTRACT

The objective of the Aakam360 website is to provide a centralized platform for showcasing architectural and interior design services. We aim to enhance user engagement and experience by introducing two new features: a chatbot and feedback videos. A chatbot designed to provide instant support for newly users and feedback videos for user experience and opinions about a product or service. The website facilitates project showcasing, client interaction, and service booking. It also enhances visibility for design professionals through digital presence for Aakam360.

PROBLEM DEFINITION

Aakam360 currently offers a wide array of functionalities, catering to diverse user needs. Despite its robust offerings, user feedback and engagement statistics highlight areas needing improvement. Users have expressed the need for more immediate support options and a more interactive way to provide feedback.

LITERATURE SURVEY

Foundations of Responsive Design

- The concept of responsive web design was first introduced by Ethan Marcotte (2010). It involves the use of flexible grids, flexible images, and media queries to adapt web layouts to different screen sizes and orientations.
- Responsive design ensures that:
 - Websites function effectively on desktops, tablets, and mobile phones.
 - Content is readable without zooming or horizontal scrolling.
 - Layouts dynamically adjust based on screen resolution, enhancing usability.
- Aakam360 applies these principles using React.js and CSS media queries, ensuring that its components (e.g., mentor cards, event listings, carousels) rearrange and resize based on the user's device.

LITERATURE SURVEY

Mobile-First and Progressive Enhancement

- Modern design strategies advocate for a mobile-first approach, where developers design for small screens initially and enhance for larger devices. This is crucial in regions where users access the internet primarily through smartphones. Luke Wroblewski (2011) emphasized designing the most constrained version first to
- focus on core functionality. Progressive enhancement ensures that users with limited device capabilities still receive a functional and readable interface. Aakam360 follows this approach by making all critical features
- —like internships, event access, chatbot usage, and contact forms—fully functional on smaller screens first.

LITERATURE SURVEY

Accessibility Standards and Guidelines

- Accessibility ensures that digital content can be used by people with disabilities, including those who are visually or motor-impaired. The Web Content Accessibility Guidelines (WCAG) 2.1, published by the W3C, outlines strategies for inclusive web design.
- Key principles include:
- Perceivable: Information and UI must be presented in ways users can perceive (e.g., text alternatives for images).
- Operable: Interface components must be usable via keyboard and assistive devices.
- Understandable: Content must be readable and navigable.
- Robust: Content should work across various browsers and assistive technologies.

LITERATURE SURVEY

Front-End Frameworks and Tools

- Several tools support responsive and accessible web development:
- React.js (used in Aakam360) allows building modular, stateful, and accessible components.
- Tailwind CSS and Bootstrap provide pre-defined classes for mobile responsiveness and accessibility.
- ARIA (Accessible Rich Internet Applications) roles are used for making dynamic components like modals, accordions, and carousels more accessible.
- Aakam360 uses Tailwind CSS and custom components that implement:
- Hover/focus-visible states
- ARIA roles in components like dropdowns, navigation menus, and buttons
- Tab-based navigation to improve accessibility for users without a mouse.
